# Chapter 7: Perturbative Effective Slip Lengths

Nat Lund

October 16, 2013

We derived an expression for the effective slip length using the homogenization technique; this is presented in the previous chapter. However, prior to doing this, we derived an expression for the effective slip length using a different technique – the method of perturbation. The homogenized expression for  $b_{\rm eff}$  holds for a non-flat surface, while the perturbative expression assumes a flat surface. Thus, the homogenized  $b_{\rm eff}$  subsumes the perturbative  $b_{\rm eff}$  as a special case. The derivation of  $b_{\rm eff}$  by perturbation methods is presented here.

We model the fluid system as incompressible, Stokes 'creeping' flow, with velocity vector  $\vec{u} = (u, v, w)$ :

$$\nabla^2 \vec{u} = \frac{1}{\mu} \nabla p \tag{1}$$

$$\nabla \cdot \vec{u} = 0 \tag{2}$$

The bottom solid surface is modeled as the z=0 plane. The surface is **flat**, so simple Navier slip holds:

$$u(0) = b(x, y) \frac{\partial u}{\partial z}|_{z=0}$$
(3)

The intrinsic slip length of the surface b(x, y) is a rectangular-periodic function, with period L in the x direction. Flow is generally in the x direction, driven by shear *only*. Therefore there is no pressure gradient, and the pressure has the same x-periodicity as the surface:

$$p(x, y, z) = p(x + L, y, z)$$

$$\tag{4}$$

Note that the Navier slip condition is scalar, while the bulk conditions are vector equations. This is because only the x velocity slip effect is relevant to our analysis.

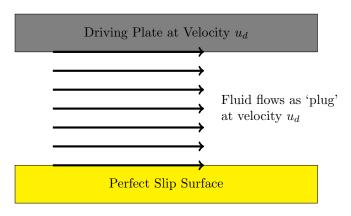

## Plug Flow

Our method is to perturb the exact case of plug flow. If fluid is shear-driven by a constant velocity plate at the top boundary, and experiences **perfect slip** at the bottom boundary:

$$u(x, y, \text{top}) = u_d \text{ (constant)}$$
 (5)

$$\frac{\partial u}{\partial z}|_{z=0} = 0 \tag{6}$$

then the fluid has no resistance at the bottom, so the entire bulk quickly accelerates up to velocity of the driving plate. So fluid flows as a **plug** of fluid all at the same velocity.

# Perturbed Plug Flow

3-5

The **boundary layer** is the thin layer of fluid on the surface, where flow is affected by the surface patterning. Above the boundary layer, the flow is uniform laminar flow, with effects due to the surface heterogeneity washed out. Let d be the height of the boundary layer.

Velocity at d is (arbitrarily close to) constant and in the x direction only. Call this constant x velocity  $u_d$ .

$$\vec{u}(x, y, d) = (u_d, 0, 0), \qquad u(x, y, d) = u_d$$
 (7)

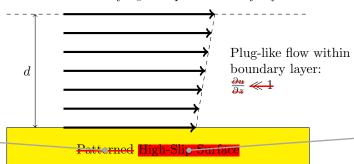

We now consider a boundary layer with flow that is perturbed slightly away from true plug flow. What does it mean for a flow to be  $close\ to$  plug flow?

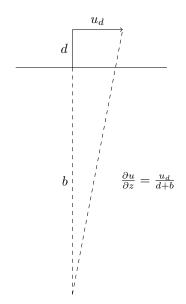

Since plug flow is shear-free, we can characterise plug-like flow as having a very small shear rate:

 $\frac{\partial u}{\partial z} \ll 1$  (8)

3-7

Uniform velocity  $u_d$  at top of boundary layer

Geometrically

$$\frac{u}{dz} \equiv \frac{u_d}{d+b} \tag{9}$$

In Appendix C we show that if the length scale of the surface pattern is fixed, then  $\vec{a}$  may scale as  $u_d$ . In that case, the ratio  $u_d/d$  is constant, while b is variable. So:

$$\frac{u_d}{d+b} = \frac{\frac{u_d}{d}}{1+\frac{b}{d}} \to 0 \quad \text{if} \quad \frac{b}{d} \to \infty \quad \text{if} \quad \frac{d}{b} \to 0$$
 (10)

Thus

4-6

$$\frac{\partial u}{\partial z} \ll 1$$
 if  $\frac{d}{b} \ll 1$  (11)

Therefore let us concentrate on the worst case, where  $\frac{b}{}$  is minimal, and introduce the small parameter

$$\frac{\epsilon = \frac{d}{b_{\min}}}{, \quad \epsilon \ll 1} \tag{12}$$

where  $b_{\min}$  is the minimum slip length of the surface.

4-3

4-1

4-4

# Perturbed Navier Slip

The Navier slip condition relates the shear rate to the slip velocity. With  $\epsilon$ , we can express the slip condition as a perturbation away from shear-free plug flow. Multiplying both sides by  $\epsilon$  gives:

$$\frac{d}{b_{\min}}b(x,y)\frac{\partial u}{\partial z} = \epsilon u(0) \tag{13}$$

Define the normalised slip length:

$$\hat{b} = \frac{b(x,y)}{b_{\min}}, \qquad \hat{b} \ge 1 \tag{14}$$

So the perturbed slip condition is:

$$d\hat{b}\frac{\partial u}{\partial z} = \epsilon u(0) \tag{15}$$

# Perturbation Expansion

The velocity solution to Stokes flow is assumed to be expressible as a power series in  $\epsilon$ :

$$\vec{u} = \vec{u}_0 + \epsilon \vec{u}_1 + O(\epsilon^2) \tag{16}$$

where

$$\vec{u}_0 + \epsilon \vec{u}_1 = (u_0, v_0, w_0) + \epsilon(u_1, v_1, w_1) \tag{17}$$

The pressure is similarly expressed as a power series in  $\epsilon$ :

$$p = p_0 + \epsilon p_1 + O(\epsilon^2) \tag{18}$$

Both are inserted into the equations of Stokes flow with perturbed slip, giving to first order:

$$\nabla^2 \vec{u}_0 + \epsilon \nabla^2 \vec{u}_1 = \frac{1}{\mu} \nabla p_0 + \epsilon \frac{1}{\mu} \nabla p_1 \tag{19}$$

$$\nabla \cdot \vec{u}_0 + \epsilon \nabla \cdot \vec{u}_1 = 0 \tag{20}$$

$$p_0(x, y, z) + \epsilon p_1(x, y, z) = p_0(x + L, y, z) + \epsilon p_1(x + L, y, z)$$
(21)

$$u_0(x, y, d) + \epsilon u_1(x, y, d) = u_d \tag{22}$$

$$d\hat{b}\frac{\partial u_0}{\partial z} + \epsilon d\hat{b}\frac{\partial u_1}{\partial z} = \epsilon u_0 \tag{23}$$

#### Zeroth Order

By construction, setting  $\epsilon$  to zero gives shear-free flow:

$$\nabla^2 \vec{u}_0 = \frac{1}{\mu} \nabla p_0 \tag{24}$$

$$u_0(x, y, d) = u_d \tag{25}$$

$$\frac{\partial u_0}{\partial z}|_{z=0} = 0 \tag{26}$$

whose solution is plug flow. That is,  $u_0(x, y, z) = u_d$ , constant everywhere.

#### First Order

Cancelling the zeroth order terms and dividing by  $\epsilon$  gives the first order problem:

$$\nabla^2 \vec{u}_1 = \frac{1}{\mu} \nabla p_1 \tag{27}$$

$$\nabla \cdot \vec{u}_1 = 0 \tag{28}$$

$$p_1(x, y, z) = p_1(x + L, y, z)$$
(29)

$$u_1(x, y, d) = 0 (30)$$

$$d\hat{b}\frac{\partial u_1}{\partial z}|_{z=0} = u_0 = u_d \tag{31}$$

Note that the zeroth order solution appears in the slip condition.

The standard way to eliminate the pressure is to use the vorticity  $\nabla \times \vec{u}$ . Taking the curl of both sides of the Stokes equation gives:

$$\nabla \times \nabla^2 \vec{u}_1 = \nabla \times \frac{1}{\mu} \nabla p_1 \tag{32}$$

The right hand side is identically zero, leaving  $\nabla \times \nabla^2 \vec{u}_1 = 0$ . Recall that the vector Laplacian is:

$$\nabla^2 \vec{u}_1 = (\nabla^2 u_1, \nabla^2 v_1, \nabla^2 w_1) \tag{33}$$

so that  $\nabla \times \nabla^2 \vec{u}_1 = 0$  is

$$\left(\frac{\partial}{\partial y}\nabla^2 w_1 - \frac{\partial}{\partial z}\nabla^2 v_1, \frac{\partial}{\partial z}\nabla^2 u_1 - \frac{\partial}{\partial x}\nabla^2 w_1, \frac{\partial}{\partial x}\nabla^2 v_1 - \frac{\partial}{\partial y}\nabla^2 u_1\right) = (0, 0, 0)$$
(34)

This gives three PDEs. It turns out that the successfull strategy is to use the last two. Expanding out the Laplacian operator, these are:

$$\frac{\partial^3 u_1}{\partial z \partial x^2} + \frac{\partial^3 u_1}{\partial z \partial y^2} + \frac{\partial^3 u_1}{\partial z^3} = \frac{\partial^3 w_1}{\partial x^3} + \frac{\partial^3 w_1}{\partial x \partial y^2} + \frac{\partial^3 w_1}{\partial x \partial z^2}$$
(35)

$$\frac{\partial^3 u_1}{\partial y \partial x^2} + \frac{\partial^3 u_1}{\partial y^3} + \frac{\partial^3 u_1}{\partial y \partial z^2} = \frac{\partial^3 v_1}{\partial x^3} + \frac{\partial^3 v_1}{\partial x \partial y^2} + \frac{\partial^3 v_1}{\partial x \partial z^2}$$
(36)

It also happens that the successful strategy is to convert to last equation into an expression in  $u_1$  and  $w_1$ . We can do this because the incompressibility couples u, v and w. Specifically, the continuity equation  $\nabla \cdot \vec{u}_1 = 0$  can be rearranged to:

$$\frac{\partial v_1}{\partial y} = -\frac{\partial u_1}{\partial x} - \frac{\partial w_1}{\partial z} \tag{37}$$

To use this substitution, we first differentiate the last equation with respect to y:

$$\frac{\partial^4 u_1}{\partial y^2 \partial x^2} + \frac{\partial^4 u_1}{\partial y^4} + \frac{\partial^4 u_1}{\partial y^2 \partial z^2} = \frac{\partial^4 v_1}{\partial y \partial x^3} + \frac{\partial^4 v_1}{\partial x \partial y^3} + \frac{\partial^4 v_1}{\partial x \partial y \partial z^2}$$
(38)

then make the substitution, giving:

$$\frac{\partial^{4} u_{1}}{\partial y^{2} \partial x^{2}} + \frac{\partial^{4} u_{1}}{\partial y^{4}} + \frac{\partial^{4} u_{1}}{\partial y^{2} \partial z^{2}} =$$

$$- \frac{\partial^{3}}{\partial x^{3}} \left[ \frac{\partial u_{1}}{\partial x} + \frac{\partial w_{1}}{\partial z} \right] - \frac{\partial^{3}}{\partial x \partial y^{2}} \left[ \frac{\partial u_{1}}{\partial x} + \frac{\partial w_{1}}{\partial z} \right] - \frac{\partial^{3}}{\partial x \partial z^{2}} \left[ \frac{\partial u_{1}}{\partial x} + \frac{\partial w_{1}}{\partial z} \right] \quad (39)$$

Simplified:

$$\begin{split} \frac{\partial^4 u_1}{\partial x^4} + 2 \frac{\partial^4 u_1}{\partial x^2 \partial y^2} + \frac{\partial^4 u_1}{\partial y^4} + \frac{\partial^4 u_1}{\partial x^2 \partial z^2} + \frac{\partial^4 u_1}{\partial y^2 \partial z^2} = \\ - \frac{\partial^4 w_1}{\partial x^3 \partial z} - \frac{\partial^4 w_1}{\partial x \partial y^2 \partial z} - \frac{\partial^4 w_1}{\partial x \partial z^3} \end{split} \tag{40}$$

7-2

Thus we have two PDEs in two variables,  $u_1$  and  $w_1$ .

$$\frac{\partial^3 u_1}{\partial z \partial x^2} + \frac{\partial^3 u_1}{\partial z \partial y^2} + \frac{\partial^3 u_1}{\partial z^3} = \frac{\partial^3 w_1}{\partial x^3} + \frac{\partial^3 w_1}{\partial x \partial y^2} + \frac{\partial^3 w_1}{\partial x \partial z^2}$$
(41)

$$\frac{\partial^4 u_1}{\partial x^4} + 2 \frac{\partial^4 u_1}{\partial x^2 \partial y^2} + \frac{\partial^4 u_1}{\partial y^4} + \frac{\partial^4 u_1}{\partial x^2 \partial z^2} + \frac{\partial^4 u_1}{\partial y^2 \partial z^2} = -\frac{\partial^4 w_1}{\partial x^3 \partial z} - \frac{\partial^4 w_1}{\partial x \partial y^2 \partial z} - \frac{\partial^4 w_1}{\partial x \partial z^3} \tag{42}$$

#### Fourier Series

Because the flow is periodic, it is natural to write  $u_1$  as a Fourier series:

$$u_1(x, y, z) = \sum_{\vec{k}}^{\infty} U_{\vec{k}}(z) \exp(i\vec{k} \cdot \vec{r})$$
(43)

where  $\vec{r} = (x, y)$  and the wave vector  $\vec{k}$  is a reciprocal lattice vector defined by integers p and q:

$$\vec{k} = (m, n) = (2\pi p, 2\pi q), \qquad k^2 = m^2 + n^2$$
 (44)

The Fourier coefficient is:

$$U_{\vec{k}}(z) = \frac{1}{L^2} \int_0^L \int_0^L u(x, y, z) \exp(i\vec{k} \cdot \vec{r}) \, dx dy \tag{45}$$

Similarly for  $w_1$ :

$$w_1(x, y, z) = \sum_{\vec{k}}^{\infty} W_{\vec{k}}(z) \exp(i\vec{k} \cdot \vec{r})$$
(46)

The two Fourier expansions for velocity are inserted into the two PDEs. At this point, resulting mess of algebra was tackled with the computer algebra package Maple.

At length, one has two expressions that are true for arbitrary  $\vec{r} = (x, y)$ . As a consequence, the following two ODEs in U and W are true for all  $\vec{k}$ :

$$\frac{d^3U}{dz^3} - k^2 \frac{dU}{dz} = i \left( \frac{d^2W}{dz^2} - k^2W \right) m \tag{47}$$

$$k^{2} \frac{d^{2}U}{dz^{2}} - k^{4}U = i \left( \frac{d^{3}W}{dz^{3}} - k^{2} \frac{dW}{dz} \right) m \tag{48}$$

(The parameters k and m are of course not independent.)

# Solving the DEs

It turns out that a successful strategy is to solve for W(z) first, then substitute the solution back into Equation (47), allowing us to solve for U(z).

# Solve for W(z)

After multiplying Equation (47) by  $k^2$ , and differentiating Equation (48) with respect to z, the two equations may be combined to:

$$\frac{d^4W}{dz} - 2k^2 \frac{d^2W}{dz^2} + k^4W = 0 (49)$$

The general solution of which is:

$$W(z) = (P_{\vec{k}} + Q_{\vec{k}}z) e^{-kz} + (R_{\vec{k}} + S_{\vec{k}}z) e^{kz}$$
(50)

Now, at the top of the boundary layer, flow is defined to be in the x direction only. Therefore  $w_1(x, y, d) = 0$ , which requires that

$$W(d) = 0 (51)$$

The  $e^{kz}$  term of W(z) is obviously a problem, since  $e^{kd}$  increases rapidly with increasing d. Therefore we must have  $R_{\vec{k}} = S_{\vec{k}} = 0$ .

Furthermore, the bottom surface is impermeable, so  $w_1(x, y, 0) = 0$ , which requires that W(0) = 0. An immediate corollary is that  $W(0) = P_{\vec{k}} = 0$ . We are left with:

$$W(z) = Q_{\vec{k}} z e^{-kz} \tag{52}$$

# Solving for U(z)

We insert the solution for W(z) into Equation (48), yielding an ODE in U(z):

$$\frac{d^3U}{dz^3} - k^2 \frac{dU}{dz} = iQ_{\vec{k}} m k^2 e^{-kz}$$
 (53)

For non-zero k, the general solution is:

$$U_{\vec{k}}(z) = \left(P_{\vec{k}} + iQ_{\vec{k}}\frac{m}{k^2}\right)e^{-kz} + B_{\vec{k}}e^{kz}$$
(54)

For k = 0, the ODE reduces to:

$$\frac{d^3U}{dz^3} = 0\tag{55}$$

whose solution is:

$$U_0 = A_0 + B_0 z + C_0 z^2 (56)$$

# Assemble $u_1(x, yz)$ solution

We have found the Fourier coefficients in their most general form. We now insert them into the Fourier series expression  $u_1(x,y,z) = \sum_{\vec{k}}^{\infty} U_{\vec{k}}(z) \exp(i\vec{k}\cdot\vec{r})$ :

$$u_1(x, y, z) = A_0 + B_0 z + C_0 z^2 + \sum_{k \neq 0} \left( A_{\vec{k}} e^{-kz} + B_{\vec{k}} e^{kz} \right) \exp(i\vec{k} \cdot \vec{r})$$
 (57)

where 
$$A_{\vec{k}} = \left(P_{\vec{k}} + iQ_{\vec{k}}\frac{m}{k^2}\right)$$
 (58)

# Use periodicity to eliminate $C_0$

Inserting our expression for  $u_1(x, y, z)$  into the x component of the Stokes equation:

$$\frac{\partial^2 u_1}{\partial x^2} + \frac{\partial^2 u_1}{\partial y^2} + \frac{\partial^2 u_1}{\partial z^2} = \frac{1}{\mu} \frac{\partial p_1}{\partial x}$$
 (59)

gives:

$$-m^{2} \sum_{k \neq 0} \left( A_{\vec{k}} e^{-kz} + B_{\vec{k}} e^{kz} \right) \exp(i\vec{k} \cdot \vec{r}) - n^{2} \sum_{k \neq 0} \left( A_{\vec{k}} e^{-kz} + B_{\vec{k}} e^{kz} \right) \exp(i\vec{k} \cdot \vec{r})$$

$$+2C_0 + k^2 \sum_{k \neq 0} (A_{\vec{k}} e^{-kz} + B_{\vec{k}} e^{kz}) \exp(i\vec{k} \cdot \vec{r}) = \frac{1}{\mu} \frac{\partial p_1}{\partial x}$$
 (60)

Since  $k^2 = m^2 + n^2$ , this reduces to:

$$2C_0 = \frac{1}{\mu} \frac{\partial p_1}{\partial x} \tag{61}$$

Integrate this over one period:

$$\int_0^L 2C_0 \, dx = \int_0^L \frac{1}{\mu} \frac{\partial p_1}{\partial x} \, dx \tag{62}$$

$$2C_0L = \frac{1}{\mu}[p_1(L, y, z) - p_1(0, yz)] = 0$$
(63)

The flow is shear-driven only, so the pressure is periodic:  $p_1(x, y, z) = p_1(x + L, y, z)$ . Therefore the right-hand side of the integral vanishes, and we are left with  $C_0 = 0$ .

#### Use top-of-boundary-layer condition to find $A_0$

At the top of the boundary layer, the flow is (arbitrarily close to) uniform laminar flow with velocity  $u_d$  in the x direction only. Above the boundary layer, the zeroth order solution is exact, so the first order term vanishes:

$$u_1(x, y, d) = 0 (64)$$

Inserting our expression gives:

$$A_0 + B_0 d + \sum_{k \neq 0} \left( A_{\vec{k}} e^{-kd} + B_{\vec{k}} e^{kd} \right) \exp(i\vec{k} \cdot \vec{r}) = 0$$
 (65)

The height d of the boundary layer is essentially chosen to be large enough that the  $u_1(x, y, d)$  term is arbitrarily small. This works for the  $e^{-kd}$  term; it can be made arbitrarily small with increasing d. But the  $B_{\vec{k}}e^{kd}$  term gets arbitrarily large with increasing d. Therefore, we require that  $B_{\vec{k}} = 0$  for all  $k \neq 0$ .

Then the sum term is negligible, and we are left with:

$$A_0 + B_0 d = 0 (66)$$

from which it follows that  $A_0 = -B_0 d$ . Our first-order velocity term is now:

$$u_1(x, y, z) = B_0(z - d) + \sum_{k \neq 0} (A_{\vec{k}} e^{-kz}) \exp(i\vec{k} \cdot \vec{r})$$
 (67)

# Use Slip Boundary Condition to find $B_0$

We have found that the Fourier coefficient for  $\vec{k} = (0,0)$  is  $U_0 = B_0(z-d)$ . We may equate this with the formal definition:

$$U_0 = B_0(z - d) = \frac{1}{L^2} \int_0^L \int_0^L u_1(x, y, z) \, dx dy \tag{68}$$

and differentiate with respect to z:

$$\frac{d}{dz}(B_0z - B_0d) = \frac{1}{L^2} \int_0^L \int_0^L \frac{d}{dz} u_1(x, y, z) \, dxdy \tag{69}$$

then evaluate at z = 0:

$$B_0 = \frac{1}{L^2} \int_0^L \int_0^L \frac{du_1}{dz}|_{z=0} dxdy \tag{70}$$

At this point we can substitute the slip boundary condition:

$$\frac{du_1}{dz}|_{z=0} = \frac{1}{d\hat{b}}u_d \tag{71}$$

to get:

$$B_0 = \frac{1}{L^2} \int_0^L \int_0^L \frac{1}{d\hat{b}} u_d \, dx dy \tag{72}$$

The double integral is the area-weighted average:

$$B_0 = \frac{u_d}{d} \frac{1}{L^2} \int_0^L \int_0^L \frac{1}{\hat{b}} dx dy = \frac{u_d}{d} \left\langle \frac{1}{\hat{b}} \right\rangle \tag{73}$$

So the first order velocity term is:

$$u_1(x,y,z) = \frac{u_d}{d} \left\langle \frac{1}{\hat{b}} \right\rangle (z-d) + \sum_{k \neq 0} \left( A_{\vec{k}} e^{-kz} \right) \exp(i\vec{k} \cdot \vec{r})$$
 (74)

# **Bolt Together Velocity Solution**

We now have all the parts of the x velocity perturbaton expansion  $u(x, y, z) = u_0(x, y, z) + \epsilon u_1(x, y, z)$ . Bolting it together gives:

$$u(x,y,z) = u_d + \epsilon \frac{u_d}{d} \left\langle \frac{1}{\hat{b}} \right\rangle (z-d) + \epsilon \sum_{k \neq 0} \left( A_{\vec{k}} e^{-kz} \right) \exp(i\vec{k} \cdot \vec{r})$$
 (75)

Recall that:

$$\epsilon = \frac{d}{b_{\min}} \quad \text{and} \quad \hat{b} = \frac{b}{b_{\min}}$$
(76)

therefore:

$$\epsilon \frac{u_d}{d} \left\langle \frac{1}{\hat{b}} \right\rangle = \frac{d}{b_{\min}} \frac{u_d}{d} \left\langle \frac{b_{\min}}{b} \right\rangle = u_d \left\langle \frac{1}{b} \right\rangle$$
(77)

Thus, the final velocity solution is:

$$u(x,y,z) = u_d + u_d \left\langle \frac{1}{b} \right\rangle (z-d) + \epsilon \sum_{k \neq 0} \left( A_{\vec{k}} e^{-kz} \right) \exp(i\vec{k} \cdot \vec{r})$$
 (78)

## Effective Slip Length

Since we know the height d of the boundary layer and the velocity  $u_d$  at the top of the boundary layer, if we know the shear rate at top of the boundary layer, we can calculate the effective slip length.

The flow is uniform and laminar above the boundary layer, so simple shear obtains, and the shear rate is simply the velocity gradient  $\frac{d}{dz}u$ :

$$\frac{d}{dz}u(x,y,z) = u_d \left\langle \frac{1}{b} \right\rangle - \epsilon \sum_{k \neq 0} \left( kA_{\vec{k}}e^{-kz} \right) \exp(i\vec{k} \cdot \vec{r})$$
 (79)

By construction, for z at (and above) d, the  $e^{-kz}$  term is negligible. So:

$$\frac{du}{dz}|_{z=d} = u_d \left\langle \frac{1}{b} \right\rangle \tag{80}$$

Rearranging to the familiar form of Navier slip:

$$u_d = \left\langle \frac{1}{b} \right\rangle^{-1} \frac{du}{dz} |_{z=d} \tag{81}$$

This defines the effective slip length of a virtual surface at the top of the boundary layer:

$$b_{\text{eff}} = \left\langle \frac{1}{b} \right\rangle^{-1} \tag{82}$$

The true slip length of the **solid surface** is less by the thickness of the boundary layer:

$$b_{\text{eff}} = \left\langle \frac{1}{b} \right\rangle^{-1} - d \tag{83}$$

Now, in the homogenization technique, we took the limit of the period of the surface patterning diminishing to zero. This is equivalent to the limit of the thickness of the boundary layer diminishing to zero. Therefore, the perturbed effective slip length reconciles with the homogenized slip length.

$$\lim_{d \to 0} b_{\text{eff}} = \left\langle \frac{1}{b} \right\rangle^{-1} \tag{84}$$

# Perturbed Couette Flow

A similar analysis can be done for perturbed Couette flow.

In this case, flow is *close to* Couette flow if the maximum slip length  $b_{\text{max}}$  of the surface is *small* compared to the height d of the boundary layer. Therefore a suitable choice of perturbation parameter is:

$$\epsilon = \frac{b_{\text{max}}}{d} \tag{85}$$

And the normalised slip length can be defined as:

$$\hat{b} = \frac{b(x,y)}{b_{\text{max}}}, \qquad 0 \le \hat{b} \le 1 \tag{86}$$

Then both sides of the Navier slip condition can be divided by  $\epsilon$ :

$$\frac{1}{\epsilon}u(x,y,0) = \frac{d}{b_{\text{max}}}b(x,y)\frac{\partial u}{\partial z}|_{z=0}$$
(87)

So the perturbed slip condition is:

$$u(x, y, 0) = \epsilon d\hat{b} \frac{\partial u}{\partial z}|_{z=0}$$
(88)

As before, the velocity solution is written as a perturbation expansion:

$$\vec{u} = \vec{u}_0 + \epsilon \vec{u}_1 = (u_0, v_0, w_0) + \epsilon(u_1, v_1, w_1)$$
(89)

which is inserted into the Stokes, continuity, and various boundary equations. The only difference is of course the slip condition. To first order in  $\epsilon$ :

$$u_0 + \epsilon u_1 = \epsilon d\hat{b} \frac{\partial u_0}{\partial z}|_{z=0} \tag{90}$$

#### Zeroth Order

By construction, setting  $\epsilon = 0$  gives classic Couette flow:

$$u_0(x, y, d) = u_d \tag{91}$$

$$u_0(x, y, 0) = 0 (92)$$

whose solution is a linear interpolation between the top and no-slip boundary conditions:

$$u_0(x, y, z) = \frac{u_d}{d}z\tag{93}$$

#### First Order

Cancelling the zeroth order terms and dividing by  $\epsilon$  gives the first order slip condition:

$$u_1 = d\hat{b}\frac{\partial u_0}{\partial z}|_{z=0} = d\hat{b}\frac{u_d}{d}$$
(94)

$$u_1 = \hat{b}u_d \tag{95}$$

Again, the zeroth order solution enters the slip condition.

The analysis proceeds exactly as before, until the point where we solve for the coefficient  $B_0$ .

# Use Slip Boundary Condition to find $B_0$

We have found that the Fourier coefficient for  $\vec{k} = (0,0)$  is  $U_0 = B_0(z-d)$ . We may equate this with the formal definition:

$$U_0 = B_0(z - d) = \frac{1}{L^2} \int_0^L \int_0^L u_1(x, y, z) \, dx dy \tag{96}$$

If we evaluate this at z = 0, we may substitute the first order slip condition:

$$-B_0 d = \frac{1}{L^2} \int_0^L \int_0^L \hat{b} u_d \, dx dy \tag{97}$$

The double integral is the area-weighted average:

$$B_0 = -\frac{u_d}{d} \frac{1}{L^2} \int_0^L \int_0^L \hat{b} \, dx dy = -\frac{u_d}{d} \left\langle \hat{b} \right\rangle \tag{98}$$

So the first order velocity term is:

$$u_1(x, y, z) = \frac{u_d}{d} \left\langle \hat{b} \right\rangle (d - z) + \sum_{k \neq 0} \left( A_{\vec{k}} e^{-kz} \right) \exp(i\vec{k} \cdot \vec{r})$$
 (99)

#### **Bolt Together Velocity Solution**

We now have all the parts of the x velocity perturbaton expansion  $u(x, y, z) = u_0(x, y, z) + \epsilon u_1(x, y, z)$ . Bolting it together gives:

$$u(x,y,z) = \frac{u_d}{d}z + \epsilon \frac{u_d}{d} \left\langle \hat{b} \right\rangle (d-z) + \epsilon \sum_{k \neq 0} \left( A_{\vec{k}} e^{-kz} \right) \exp(i\vec{k} \cdot \vec{r})$$
 (100)

Recall that:

$$\epsilon = \frac{b_{\text{max}}}{d} \quad \text{and} \quad \hat{b} = \frac{b}{b_{\text{max}}}$$
(101)

therefore:

$$\epsilon \frac{u_d}{d} \left\langle \hat{b} \right\rangle = \frac{b_{\text{max}}}{d} \frac{u_d}{d} \left\langle \frac{b}{b_{\text{max}}} \right\rangle = \frac{u_d}{d^2} \left\langle b \right\rangle$$
 (102)

so that:

$$\epsilon \frac{u_d}{d} \left\langle \hat{b} \right\rangle (d-z) = \frac{u_d}{d} \left\langle b \right\rangle - \frac{u_d}{d^2} \left\langle b \right\rangle z$$
 (103)

Thus, the final velocity solution is

$$u(x, y, z) = \frac{u_d}{d} \left[ z \left( 1 - \frac{\langle b \rangle}{d} \right) + \langle b \rangle \right] + \epsilon \sum_{k \neq 0} \left( A_{\vec{k}} e^{-kz} \right) \exp(i\vec{k} \cdot \vec{r})$$
 (104)

# Effective Slip Length

As before, we calculate the effective slip length with the velocity gradient:

$$\frac{\partial}{\partial z}u(x,y,z) = \frac{u_d}{d}\left(1 - \frac{\langle b\rangle}{d}\right) - \epsilon \sum_{k \neq 0} \left(kA_{\vec{k}}e^{-kz}\right) \exp(i\vec{k}\cdot\vec{r})$$
 (105)

At z greater than d, the  $e^{-kz}$  term renders the sum term negligible, leaving:

$$\frac{\partial}{\partial z}u(x,y,z) = \frac{u_d}{d}\left(1 - \frac{\langle b\rangle}{d}\right) \tag{106}$$

Rearranging to the form of Navier slip

$$u_d = d\left(1 - \frac{\langle b \rangle}{d}\right)^{-1} \frac{\partial u}{\partial z}|_{z=0} \tag{107}$$

Implying an effective slip length at the top of the boundary of:

$$b_{\text{eff}} = d \left( 1 - \frac{\langle b \rangle}{d} \right)^{-1} = \frac{d}{1 - \frac{\langle b \rangle}{d}}$$
 (108)

The slip length of the surface is found by subtracting d from this:

$$b_{\text{eff}} = \frac{d}{1 - \frac{\langle b \rangle}{d}} - d \tag{109}$$

$$= \frac{d - d\left[1 - \frac{\langle b \rangle}{d}\right]}{1 - \frac{\langle b \rangle}{d}} = \frac{d - d + \langle b \rangle}{1 - \frac{\langle b \rangle}{d}} = \frac{\langle b \rangle}{1 - \frac{\langle b \rangle}{d}}$$
(110)

We have assumed that for Couette-like flow,  $b_{\text{max}} \ll d$ , therefore  $\langle b \rangle \ll d$ , and so  $\langle b \rangle / d$  is negligible. We are left with:

$$b_{\text{eff}} = \langle b \rangle \tag{111}$$

# Conclusion

The effective slip length found by perturbative methods reconciles with the effective slip length found by homogenization (for the case where the minimum slip length is large compared to the boundary layer thickness). Because homogenization can deal with a non-flat surface, the homogenized effective slip length subsumes the perturbative slip length.

In addition, the perturbative method can yield an effective slip length for the opposite case – where the slip lengths are small compared to surface length scales.

Notes

1-1 15/01/2014 7:30 am, Shaun Hendy

Unfortunately most of the derivation in this chapter is incorrect. You have taken a very different approach to that which we took in our papers and it is flawed.

Things go awry when you invoke your boundary layer and impose a boundary condition on it. This is an uncontrolled approximation that torpedoes your subsequent attempts to make controlled approximations.

There are also some serious mistakes in you analysis that compound this. I am afraid this chapter is going to need a serious rewrite.

15/01/2014 7:30 am, Shaun Hendy

This is not true - when b << L the perturbative approach gives beff = <b> whereas the homogenised solution gives beff=0

- 2-2 15/01/2014 7:30 am, Shaun Hendy on a flat surface
- 2-3 \[ \frac{15/01/2014 7:30 \text{ am, Shaun Hendy}}{\text{You need to refer to your previous derivations of all these equations} \]
- 2-4 15/01/2014 7:30 am, Shaun Hendy Why? You need to explain this here.
- 2-5 15/01/2014 7:30 am, Shaun Hendy

This is not a good opening sentence because you can't assume the reader knows what plug flow is. A better sentence would be: "Our approach is to consider perturbations to a flow between two surfaces one of which exhibits perfect slip while the other admits no slip. Such a flow is often referred to as plug flow."

This opening explains itself as it goes rather than expecting the reader to get to the end of the paragraph before things make sense.

- 3-1 15/01/2014 7:30 am, Shaun Hendy
  The LHS has units of frequency so can't be compared to 1.
- 15/01/2014 7:30 am, Shaun Hendy
  This doesn't have to be patterned does it?

15/01/2014 7:30 am, Shaun Hendy

15/01/2014 7:30 am, Shaun Hendy

- This doesn't have to be patterned does it?
- Again, high compared to what? You need to compare the slip length to the characteristic length of the flow that you are interested in.
- 3-4 15/01/2014 7:30 am, Shaun Hendy
  You need to be careful here because the boundary layer has a more specific meaning in fluid mechanics that is different to what you are discussing here.
- 3-5 15/01/2014 7:30 am, Shaun Hendy
  I think you are trying to say that the velocity is constant in the plane z=d.
- This is different to the usual boundary layer analysis and I worry about this approach the velocity perturbations decay exponentially so I am not sure how you would define the distance d. Is it the decay length?

I think it is better to just have a physical top surface to impose a physical boundary condition on rather than your made up one.

Notes

3-7

15/01/2014 7:30 am, Shaun Hendy

The problem is that these boundary conditions can only be approximately true, not exactly true. This messes up your perturbation analysis - how do you control the level of approximation in these boundary conditions? With this approach you can't so you have not really constructed a perturbation analysis.

You need to completely rethink your approach to this problem.

4-1 15/01/2014 7:30 am, Shaun Hendy Rephrase this.

15/01/2014 7:30 am, Shaun Hendy

I think you may have tied yourself up in knots here. You have already claimed that both d and u\_d are constant.

4-3 15/01/2014 7:30 am, Shaun Hendy
This is the shear rate at z=d?

Is it plausible that u\_d is constant in the z=d plane but the shear rate isn't? I think you have tied yourself in knots here with this boundary layer idea.

4-4 15/01/2014 7:30 am, Shaun Hendy

This is not working. You haven't told us what the magnitude of d is so it is not helpful to use it in a perturbation analysis. d is not some arbitrary number that you are free to choose - it is a physical quantity that you must solve for.

What you need to do is show that d~L, from which everything follows quite easily.

4-5 15/01/2014 7:30 am, Shaun Hendy

The LHS has units so you can't just take it to zero. You must compare it to some quantity of the same magnitude.

15/01/2014 7:30 am, Shaun Hendy

So this is now problematic. In order to satisfy (7) to an arbitrary degree of accuracy you may have to make d large, but now you are going to assume that d << b. This is going to lead to inconsistencies.

5-1 15/01/2014 7:30 am, Shaun Hendy

Epsilon is not independent of d. If you set epsilon to zero, but d is to remain finite then remember you are assuming b >> d.

6-1 15/01/2014 7:30 am, Shaun Hendy

Because this is standard you can probably skip some of the detail.

15/01/2014 7:30 am, Shaun Hendy

This is wrong - your k is dimensionless (as you say p and q are integers) whereas r has dimensions of length, so in your formulation k dot r has units of length. However, k dot r must be dimensionless. What you have forgotten is the period L. In fact  $k \sim 2$  pi p/L where p is an integer.

7-2 15/01/2014 7:30 am, Shaun Hendy the

11-1 15/01/2014 7:30 am, Shaun Hendy What is d?
